

Evidence Update on COVID-19

This is not a clinical guideline or SOP. This is a summary of the latest evidence available internationally on the management, treatment and science underlying COVID-19 disease.

Clinical characteristics

- o Lymphopenia was indicated by multiple studies as the main observation in COVID19+ patients, even in absence of fever and cough. Useful as diagnostic marker <u>Henry Guan Qu</u>
- o Lymphocyte count is negatively associated with increased disease severity. Death occurred in those with lowest lymphocyte counts in ICU patients <u>Henry</u>
- o 1100 patients Lymphopenia on admission (89% patients), Fever (44%), Cough (68%) Guan
- o 249 patients Fever 95% patients for 10 days. 31 days for those in ICU. Chen
- 204 patients Anorexia (84%), diarrhea (30%), vomiting (1%) Pan
- In children admitted to ICU, only 3.5% had lymphopenia, 40% tachycardia, 41% pneumonia, all had preexisting conditions <u>Lu</u>
- \circ Neurological symptoms include nausea and headache $\underline{\text{Li}}$
- o Dyspnoea (shortness of breath) is main symptom in most studies (almost all patients) Juan
- Take away lots of atypical presentations (GI, neuro most have respiratory symptoms)

Incubation period

- Median incubation period 5 days, with all symptoms appearing by 11.5 days in 97.5% positive patients 14 days quarantine recommended (based on severe cases only, no asymptomatic cases included) Lauer
- Duration of onset of symptoms to hospitalisation 4(2-7) days.
- IgM And IgA antibodies against Cov2 detectable in blood after 5 days post symptom onset, and IgG after 14 days (75-95% positive rate) <u>Guo</u>

Virus

- Entry to the host cell depends on the ACE2 receptor.
- In vitro, entry can be blocked with camostat meylate (TMPRSS2), an ACE2 inhibitor (potential treatment, but all work in vitro) <u>Hoffmann</u>
- No difference in nasal swab viral load symptomatic vs. asymptomatic (Italy 5830 patients) <u>Tirani</u>

Central nervous system

- Central nervous tissue is susceptible to infection murine data shows intranasal inoculation with SARS-Cov causes neurological symptoms including cardiorespiratory circuit dysfunction. In humans this may contribute to respiratory dysfunction <u>Baig</u>
- Spreads transynaptically brains of humans and mice with SARS-Cov have virus in the brain, and heavy burden in the brain stem Li potential similarities in COVID-19

Therapy

Antiviral

o No antiviral therapy has been proven to work in humans (RCTS ongoing in China)

• Lopinavir-Ritonavir trial negative in terms of mortality, improvement and viral load <u>Cao</u>

Chloroquine – interferes with ACE2 (possible COVID-receptor)

- In vitro study showed choloquine and remedesivir effective at inhibiting viral infection when co-incubated with virus at the same time (not clinically relevant) (Wang) similar in <u>SARS</u>
- Failed in mice
- In humans hydroxychloroquine reduced viral carriage, in synergy with azithromycin (22 patients and removed ICU patients from analysis) Gautret
- <u>ICTRP</u> running an RCT (Data to be published)
- China recommends <u>500mg twice per day</u> for 10 days in all cases of COVID-19 with pneumonia, but the data behind this is not published and the article is in Chinese
